EFFECTS OF TITANIA AND SINTERING TEMPERATURE ON THE PHASE DEVELOPMENT AND PROPERTIES OF SINTERED MULLITE-CARBON COMPOSITE SYNTHESIZED FROM OKPELLA KAOLIN

Abstract: The effects of the addition of titania and sintering temperatures on the phases developed, physical and mechanical properties of sintered ceramic composite produced from kaolin and spent graphite electrode was investigated. The kaolin and graphite of known mineralogical composition were thoroughly blended with 2 and 4 (vol.) % titania. From the homogeneous mixture of kaolin, graphite and titania, standard samples were prepared via uniaxial compaction. The test samples produced were subjected to firing (sintering) at 1300˚C, 1400˚C and 1500˚C. The sintered samples were characterized for the developed phases using x-ray diffractometry analysis, microstructural morphology using ultra-high resolution field emission scanning electron microscope (UHRFEGSEM) various physical and mechanical properties were determined. It was observed that microstructural morphology of the samples revealed the evolution of mullite, cristobalite and microcline. The mineralogical phase of the samples revealed the increments in the evolution of mullite and also the variation in other phase attained as the sintering temperature was raised from 1300˚C to 1500˚C for the sample having the same composition. It was concluded that the optimum mechanical property of the ceramic samples produced was achieved with sample that contain 4 (vol.) % titania and sintered at 1300˚C.

Keywords: titania; kaolin; carbon; sintering temperatures; phases developed; sintered ceramic composite

INTRODUCTION

Mullite-carbon composites find increasing applications as refractories in the context of recent developments in ceramic industry for high temperature applications [1]. These refractories exhibit in general a complex microstructure characterized by crystalline phases of different thermal expansion coefficients, physical and mechanical property. There is a current limited understanding about the effect of microstructural features, including residual thermal stresses, on the overall performance of mullite-carbon ceramic composite at high temperature. Previous researches have exploit mullite-zirconia and the addition of various additives which have been widely used for high-temperature applications due to their superior physico-mechanical properties [2]. This composite will compete with the existing mullite-zirconia in its area of applications. Recently, many researchers have focused their investigations on how to improve the properties of ceramics for various applications; Rendtorff et al. (2008) [3] used two different processing routes: for the preparation of zirconia-mullite composites, which are reaction sintering of alumina and zircon and direct sintering of mullite-zirconia grains by slip casting and sintered at 1600˚C for 2 hours. Badiee et al. (2001) [4] studied the effect of CaO, MgO, TiO₂, and ZrO₂ on mullitization of the Iranian and alusite located in Hamedan mines. They found out that the first three of these additives encouraged mullite formation from and alusite. Ebadzadeh and Ghasemi, (2002) [5] prepared zirconia-mullite composites using α-alumina and aluminium nitrate and zircon powder with TiO₂ as additive. Aramide et al. (2014) [6] synthesized mullite-zirconia composites containing yttria as additive. Chandra et al. (2013) [7] prepared zirconia-toughened ceramics with a mullite matrix based on the quaternary system ZrO₂-Al₂O₃-SiO₂-TiO₂ in the temperature range 1450-1550˚C using zircon-alumina-titania mixtures. Aksel and Komiczyn, (2001) [8] studied the influence of zircon on the mechanical properties and thermal shock behaviour of slip-cast alumina-mullite refractories.
Furthermore, Jiang et al. (2011) [9] demonstrated that the role of additives can be rationalized in terms of promotion of sintering process, formation of new phases and influence on lattice constant of aluminum titanate ceramics. Dong et al. (2008) [10], specified the effect of both single additives (MgO, SiO₂, Fe₂O₃ and ZrO₂) and compound additives on the mechanical and thermal properties of aluminum titanate ceramics, and finally pointed out that the compound additives of MgO and Fe₂O₃ have an excellent improvement on the stability of aluminum titanate. Aramide et al. (2016) [11] had synthesized mullite-carbon composite from the same materials without any additive. The objective of the present work is to improve the properties of the mullite-carbon ceramic composite through the use of titania.

MATERIALS AND METHODS

Raw Materials
Clay sample used for this study (as mine Kaolin sample) was sourced from Okpella, Edo State southern part of Nigeria, Graphite and titania (TiO₂) were sourced from (Pascal Chemicals, Akure), these were used to maintain the granulometry of the mixture.

Method

Processing of raw materials (Graphite & Kaolin)
The raw materials (Spent graphite electrode and kaolin) were crushed into a coarse particle size, of about 10 mm for graphite and less than 2 mm for kaolin; the crushed samples were further reduced by grinding using Herzog rod mill. The powdered samples were sieved using 600μm sizes aperture according to ASTM standards in an electric sieve shaker. The undersize that passed through the 600μm sieve aperture were used in the samples making.

Phase and Mineralogical Composition of Raw Kaolin and Graphite
The kaolin clay and graphite electrode samples were carefully prepared for these analyses by digesting in reagents as described by Nabil and Barbara, (2012) [12]. The mineralogical phases present in the samples were determined using X-ray diffractometry (XRD). The samples were prepared for XRD analysis using a back loading preparation method. They were analyzed using a PANalytical X'Pert Pro powder diffractometer with X'Celerator detector and variable divergence- and receiving slits with Fe filtered Co-Kα radiation. The phases were identified using X'Pert Highscore plus software. The receiving slit was placed at 0.040°. The counting area was from 5 to 70° on a 2θ scale. The count time was 1.5s. The temperature-scanned XRD data were obtained using an Anton Paar HTK 16 heating chamber with Pt heating strip Graphical representations of the qualitative result follow below.

The relative phase amounts (weight %) was estimated using the Rietveld method (Autoquan Program) as reported by Young et al [13]. Amorphous phases, if present were not taken into consideration in the quantification. The phases are reported in Figures 1 and 2 and also in Table 1.

Experimental Procedure

Composition calculation using the Rule of Mixtures Technique
Rule of Mixtures is a method of approach to approximate estimation of composite material properties, based on an assumption that a composite property is the volume weighed average of the phases (matrix and dispersed phase). According to Rule of Mixtures [14] the density of composite materials are estimated as follows:

\[ \rho_{\text{mixture}} = W_{\text{f,kaolin}} \times \rho_{\text{kaolin}} + W_{\text{f,graphite}} \times \rho_{\text{graphite}} \]  
\[ M_{\text{mixture}} = \rho_{\text{mixture}} \times \text{vol. mould} \]

where: \( \rho_{\text{mixture}} \) is the density of the mixture, \( M_{\text{mixture}} \) is the mass of the mixture, \( W_{\text{f,kaolin}} \) is the weight fraction of kaolin, \( \rho_{\text{kaolin}} \) is the density of kaolin, \( W_{\text{f,graphite}} \) is the weight fraction of graphite, \( \rho_{\text{graphite}} \) is the density of graphite and \( \text{vol. mould} \) is volume of mould.
Composites Production

The raw materials in the samples making were 3:2vol. % of kaolin and graphite respectively with the addition of 2 and 4 (vol.) % titania respectively. The mixture were blended thoroughly for proper distribution of constituents materials in a ball mill for 3 hours at a speed of 72 rev/min after weighing via electronic weighing balance in accordance with the composition calculation initially prepared [11, 15]. The resulting blended compositions were mixed with 10% water of the amount of kaolin content in each composition, this was in order to enhance the plasticity of the mixture during compaction. The mixed samples were subjected to uniaxial compaction, which was carried out mechanically under pressure. The moulded materials were fired at varying temperatures (1300°C, 1400°C and 1500°C). After which the samples were subjected to various test, to examine the phase analysis, evaluate their physical and mechanical properties.

Sintering Process

The molded materials were fired at varying temperatures (1300°C, 1400°C and 1500°C) in an electric furnace. The rate of firing differs with increased temperature (room temperature to 500°C the sintering rate was 25°C/minute, 501°C to 1000°C the sintering rate was 10°C/minute while above 1000°C the sintering rate was 1°C/minute). On reaching the various sintering temperatures, the samples were held for one hour at the temperature before the furnace was switch off and the temperatures, the samples were held for one hour at the temperature for 24 hours. The sample was then suspended in a beaker containing water in order to be completely submerged without touching the bottom of the vessel in which it is suspended. The vessel was then heated slowly so that the water boiled after heating. After boiling for about an hour with the evaporated water replaced, the sample was allowed to cool at room temperature for 24 hours. The sample was then renamed, blotted and then reweighed [15]. The percentage water absorption was calculated as showed below:

\[
\text{% water absorption} = \frac{(\text{soaked wt} - \text{dried wt})}{(\text{dried wt})} \times 100
\]

Cold Compression Strength, Modulus of Elasticity and Absorbed Energy

Cold compression strength test is to determine the compression strength to failure of each sample, an indication of its probable performance under load. The standard ceramic samples were dried in an oven at a temperature of 110°C, allowed to cool. The cold compression strength tests were performed on INSTRON 1195 at a fixed crosshead speed of 10mm min⁻¹. Samples were prepared according to ASTM C133-97 (ASTM C133-97, 2003) [6, 15] cold crushing strength, modulus of elasticity and absorbed energy of standard and conditioned samples were calculated from the equation:

\[
\text{CCS} = \frac{(\text{Load to fracture})}{(\text{Surface area of sample})}
\]

RESULTS AND DISCUSSION

Phase/Mineralogical Composition of the Raw Kaolin and Graphite Samples

The phase/mineralogical composition of the kaolin and graphite samples were characterised (investigated)
with the aid of X-ray diffractometer. The results of the phase analysis of kaolin and graphite powder quantified by XRD were presented in Table 1, Figures 1 and 2. The phase/mineralogical composition of the raw materials used have been discussed extensively in [11] they are only reported for the purpose of showing that the compositions of the starting raw materials were known.

Figure 3 to 5 which show the x-ray diffraction patterns of the samples with addition of 2% TiO₂ labelled as sample B1. While Figure 6 to 8 show the x-ray diffraction
patterns of the samples with addition of 4% TiO$_2$ to the raw kaolin and graphite, labelled as sample B2.

Plate 1. Typical SEM micrographs (Back Scattered Image) of Sample B1 showing its morphology at varied temperature (a) sample B1 at 1300˚C showing the Secondary Electron Image A = graphite phase and B = mullite phase, (b) sample B1 at 1400˚C showing the Secondary Electron Image of graphite phase and mullite phase (c) sample B1 at 1500˚C showing the Secondary Electron Image of graphite phase and C = mullite fibre Phase.

Plate 2. Typical SEM micrographs (Back Scattered Image) of Sample B2 showing its morphology at varied temperature (a) sample B2 at 1300˚C showing the Secondary Electron Image A = graphite phase and B = mullite phase, (b) sample B2 at 1400˚C showing the Secondary Electron Image of graphite phase and mullite phase (c) sample B2 at 1500˚C showing the Secondary Electron Image of graphite phase and C = mullite fibre Phase.

The XRD analysis, show that the sintered samples contains mullite, graphite, amorphous, cristobalite and microcline phases while plate 1 and 2 show the SEM morphology of the phase present in sample B1 and B2 respectively. With an increase in sintering temperature, the mullite phase of sample B1 increased rapidly from 1300˚C to 1400˚C and reduced slightly when the sintering temperature was raised to 1500˚C. Furthermore, cristobalite phase increased from 1300˚C to 1400˚C and reduced slightly when the sintering temperature was raised to 1500˚C. Amorphous phase reduced from 1300˚C to 1500˚C when the sintering temperature was raised to 1500˚C. Also, cristobalite phase increased from 1300˚C to 1400˚C and reduced slightly when the sintering temperature was raised to 1500˚C.

The graphite reduced when the sintering temperature was raised from 1300˚C to 1500˚C. Microcline increased from 1300˚C to 1400˚C and reduced slightly below the amount attained at 1300˚C when the sintering temperature was raised to 1500˚C. Amorphous phase reduced from 1300˚C to 1500˚C. Moreover, many other researchers [17-21] have reported on the various transformations occur when kaolinite is fired from temperature just below 200°C to around 1000°C; this includes dehydration, dehydroxylation and structural breakdown. As seen from Table 2, the raw Okpella kaolin’s constituents are; 63.23% kaolinite, 0.65% quartz, 36.13% amorphous which undergo a series of high temperature phase transformation as the temperature was raised from 1300-1500˚C, the sintering reactions take place via;

\[
\text{Si}_2\text{Al}_2\text{O}_5\text{(OH)}_4 \xrightarrow{420-660˚C} \text{Al}_2\text{O}_3.2\text{SiO}_2 + 2\text{H}_2\text{O}
\]

which involves the combination of two OH groups to form H$_2$O and oxygen which remains incorporated in metakaolin. At about 900˚C, metakaolinite decomposes to amorphous SiO$_2$ and γ-Al$_2$O$_3$–type spinel via

\[
\text{Al}_2\text{O}_3.2\text{SiO}_2 \xrightarrow{900˚C} \gamma\text{-Al}_2\text{O}_3 + 2\text{SiO}_2
\]

γ-Al$_2$O$_3$-type spinel and SiO$_2$ recrystallize into mullite at temperatures above 1100˚C via

\[
3\gamma\text{-Al}_2\text{O}_3 + 2\text{SiO}_2 \xrightarrow{>1100˚C} 3\text{Al}_2\text{O}_3.2\text{SiO}_2
\]

Srikrishna, et al. (1990) [22], reported the formation of a single phase (with composition close to mullite) and excess SiO$_2$ at 900˚C. Thus the formation of mullite begins at temperatures >900˚C and the process continues till 1000˚C. Kausik et al. (2004) and Omani et al. (2000) [23, 24] reported that mullitization can be increased by catalytic ions such as Fe$^{3+}$ and Ti$^{4+}$. These metallic ions help in mullite formation by replacing the Al$^{3+}$ ions in the glass structure during firing. The presence of Ti$^{4+}$ from the addition of TiO$_2$ modifies the chemical composition of the ceramic bodies and therefore the sintering behaviour is characterized by mullitization. The excess silica left during transformation of metakaolin to aluminium-silicon spinel at 925˚C-950˚C and also as a result of crystalline cristobalite formed along with platelet mullite during spinel transformation at 1050˚C.
The Effects of Titania (TiO₂) Addition on the Physical and Mechanical properties of Mullite-Carbon Ceramic Composite Samples Produced from Raw Kaolin and Graphite

Evaluation of the effects of (2 and 4) vol. % titania addition on various physical and mechanical properties of ceramic composite samples sintered at varied sintering temperature. Below are the results of various physical and mechanical properties of samples (B1, B2).

≡ Apparent Porosity

The effect of sintering temperature on the apparent porosity (AP) of Samples (B1 and B2) with varied amount (2 and 4 vol. %) of TiO₂ addition is clearly shown in Figure 9 and Table 3. From the Figure, it is observed that the apparent porosity of sample B1 (2% titania) at various sintering temperature is higher than that of the sample B2 (4% titania). It is also observed that the apparent porosity of sample B1 at 1300°C is 31.667%, as the sintering temperature increased to 1400°C the AP slightly reduced to 30.743% further increase in the sintering temperature to 1500°C leads to an increase in the apparent porosity of the sample to 31.49%. The apparent porosity of sample B2 at 1300°C is 27.289%, as the sintering temperature increased to 1400°C the AP slightly increased to 27.748% further increase in the sintering temperature to 1500°C leads to an increase in the apparent porosity of the sample to 31.309%. It is observed that the AP level of sample B1 reduced from 1300°C to 1400°C further increase in the sintering temperature to 1500°C leads to an increased in the AP. This implies that the densification of the sample continues from 1300°C to 1500°C but well pronounce at 1400°C this indicate that the maximum densification is achieved at 1400°C, an increase in the temperature from 1400°C leads to reduction in densification of the sample. For sample B2, the AP keeps increasing when the sintering temperature was raised from 1300°C to 1500°C. This implies that the densification of the sample reduces from 1300°C to 1500°C. Generally, the densification of B2 samples is better at all temperature than B1 samples. It is observed that the apparent porosity of sample B2 is better than sample A, while sample A is better than sample B1 at all temperatures. This implies that 4 vol. % titania aids densification of the sample, with less pores. According to Calister, (2007) [25] voids exist between particles of the newly formed green (unfired) ceramic, much of these inter-particles voids are eliminated during firing/sintering to produce sintered ceramic. Furthermore, according to some other researchers [16, 17, 26], the decrease in the value of AP from 1300°C to 1400°C is because of additional increase in the filling of spaces between bigger particles contained in the ceramic samples. The drastic increase in the apparent porosity from 1400°C to 1500°C is as a result of carbon reaction with oxygen, the carbon burnt off, leaving pores within the samples. According to Sadrnezhaad et al. (2006 and 2007) [27, 28] and Nemati et al. (2005) [29], high temperature oxidations of graphite lead to drastic deterioration due to graphite diminution, which result to pores in the samples.

≡ Bulk Density

The effect of sintering temperature on the bulk density of the samples (B1 and B2) with varied amount (2 and 4 vol.%) of TiO₂ addition is clearly shown in Figure 10 and Table 3. From the Figure, it is observed that the bulk density of sample B1 at 1300°C is 1.59gcm⁻³ as the sintering temperature increased to 1400°C the bulk density slightly increased to 1.667gcm⁻³ further increase in sintering temperature to 1500°C, the bulk density slightly reduced to 1.665gcm⁻³. Also, the bulk density of sample B2 at 1300°C is 1.891gcm⁻³ as the sintering temperature increased to 1400°C the bulk density slightly reduced to 1.796gcm⁻³ further increase in sintering temperature to 1500°C, the bulk density slightly reduced to 1.639gcm⁻³. The bulk density of sample B1 and B2 are dictated by their apparent porosity, the sample with less pore is more dense. Generally, it can be deduce that the bulk density of B2 samples are higher than B1 samples due to their low porosity, this implies that the addition of 4 vol. % titania aids densification of the sample than 2 vol. % titania. According to Chandra et al. (2013) [7], substantial increase in bulk density was achieved with titania addition in the compacted sintered samples, which could be related to the influence of relatively higher density of TiO₂ itself. Furthermore, according to Aramide, (2012) and Brasileiro et al. (2006) [17, 26], the increase in bulk density is because of additional increase in the filling of spaces between bigger particles contained in the ceramic samples. Summarily, samples with 4 vol. % titania (B2) attained maximum densification at 1300°C while the samples with 2 vol. % titania (B1) attained maximum densification at 1400°C.
Figure 10. Effects of Sintering Temperature on the Bulk Density of Samples with varied TiO₂ addition.

= Water Absorption
The effect of sintering temperature on water absorption of the samples (B1 and B2) with varied amount (2 and 4 vol. %) of TiO₂ addition is clearly shown in Figure 11.

From the Figure, it is observed that the water absorption of the sintered ceramic sample B1 is 21.363% at 1300°C, with an increase in temperature to 1400°C, the water absorption reduced to 19.998%. However, further increase in sintering temperature to 1500°C, the water absorption increased to 20.394%. This followed the trend recorded for apparent porosity, which implies that the water absorption of the sample reduced when the sintering temperature was increased from 1300°C to 1400°C and later increased when the sintering temperature was raised to 1500°C. For sintered ceramic sample B2, the water absorption is 17.177% at 1300°C, with an increase in temperature to 1400°C, the water absorption increased to 17.642%. However, further increase in sintering temperature to 1500°C, the water absorption increased to 19.389%. This is because high temperature transformation of mullite and cristobalite in addition to some amount of carbon burn off leads to increased porosity as a result of reduced matter content of the samples. This is due to the sintering process; according to Calister, (2007) [25] voids exist between particles of the newly formed green (unfired) ceramic, much of these inter-particles voids are eliminated during firing/sintering to produce sintered ceramic. It is observed that the water absorption of sample B1 is higher at all temperature than B2.

= Cold Crushing Strength
The effect of sintering temperature on the cold crushing strength of samples (B1 and B2) with varied amount (2 and 4 vol.% of TiO₂ addition is clearly shown in Figure 12 and Table 3. From the Figure, it is observed that the CCS of sample B1 at 1300°C is 6.76Mpa, 7.99Mpa at 1400°C and 7.65Mpa at 1500°C. This implies that with an increase in the sintering temperature, the cold crushing strength significantly increased from 1300°C to 1400°C, further increase in the sintering temperature to 1500°C leads to reduction in the CCS of the sample. Also, the CCS of sample B2 at 1300°C is 8.68Mpa, 8.47Mpa at 1400°C and 7.1Mpa at 1500°C. This implies that with an increase in the sintering temperature, the cold crushing strength significantly reduced from 1300°C to 1500°C. This showed that the highest CCS of sample B1 is achieved at 1400°C and B2 is achieved at 1300°C. Generally, the cold crushing strength of sample B2 is better compared to sample B1 at 1300°C and 1400°C, with sample B1 only better at 1500°C. The CCS results correspond to bulk density dictation which was affected by the porosity level of the sample. The reason for this is that an increase in bulk density of the sample, means that the sample contains more matter to bear the applied load [17, 18]. According to Brasileiro et al. (2006) [26], increase in CCS may be assigned to better filling of pores, higher bulk density and the increase amount of mullite that leads to improved mechanical properties.

Figure 12. Effects of Sintering Temperature on the Cold Crushing Strength of Samples with varied addition of TiO₂.

= Modulus of Elasticity
The effect of sintering temperature on the modulus of elasticity (MOE) of samples (B1 and B2) with varied amount of TiO₂ addition is clearly shown in Figure 13 and Table 3. From the Figure, it is observed that the elastic modulus of sample B1 at 1300°C is 60.43Mpa,
85.074 Mpa at 1400˚C and 82.973 Mpa at 1500˚C. This implies that with an increase in sintering temperature, the modulus of elasticity significantly increased from 1300˚C to 1400˚C, further increase in the sintering temperature to 1500˚C, the MOE slightly reduced. Also, the modulus of elasticity of sample B2 at 1300˚C is 88.884 Mpa, 88.584 Mpa at 1400˚C and 68.033 Mpa at 1500˚C. This implies that with an increase in sintering temperature, the modulus of elasticity slightly reduced from 1300˚C to 1400˚C, further increase in sintering temperature to 1500˚C, the MOE significantly reduced. Generally, the MOE of sample B2 is better compared to sample B1 at all temperatures. The MOE of the samples has the same trend with the CCS as dictated by the bulk density which was affected by the porosity level of the sample discussed earlier.

Figure 13. Effects of Sintering Temperature on the Modulus of Elasticity of Samples with varied addition of TiO₂.

= Absorbed Energy

The effect of sintering temperature on the absorbed energy (AE) of samples (B1 and B2) with varied amount of TiO₂ addition is clearly shown in Figure 13 and Table 3. From the Figure, it is observed that the absorbed energy of sample B1 at 1300˚C is 4.782 J, 5.537 J at 1400˚C and 5.488 J at 1500˚C. This implies that with an increase in sintering temperature, the absorbed energy significantly increased from 1300˚C to 1400˚C, further increase in the sintering temperature to 1500˚C, the absorbed energy slightly reduced. Also, the absorbed energy of sample B2 at 1300˚C is 6.492 J, 6.063 J at 1400˚C and 4.785 J at 1500˚C. This implies that with an increase in sintering temperature, the absorbed energy slightly reduced from 1300˚C to 1400˚C, further increase in the sintering temperature to 1500˚C, the absorbed energy significantly reduced. The modulus of elasticity results shows that except from sample B1 at 1500˚C, sample B2 has higher MOE than B1 at 1300˚C and 1400˚C. The observed variation of absorbed energy with increased sintering temperature follows the same trend with that observed for the cold crushing strength as earlier discussed.

Figure 13. Effects of Sintering Temperature on the Absorbed Energy of Samples with varied addition of TiO₂.

= Linear Expansion

The effect of sintering temperature on the linear expansion of samples (B1 and B2) with varied amount of TiO₂ addition is clearly shown in Figure 14 and Table 3. From the Figure, it is observed that the linear expansion of sample B1 is 1.018% at 1300˚C, 0.442% at 1400˚C and 2.216% at 1500˚C.

Figure 14. Effects of Sintering Temperature on the Linear Expansion of Samples with varied addition of TiO₂.
With an increase in sintering temperature, the volumetric shrinkage of sample B1 significantly increased from 1300°C to 1500°C. Also, the volumetric shrinkage of sample B2 is 4.276% at 1300°C, 3.94% at 1400°C and 2.837% at 1500°C. With an increase in sintering temperature, the volumetric shrinkage of sample B1 significantly reduced from 1300°C to 1500°C. This implies that an increase in sintering temperature aids the volumetric shrinkage of sample B1 while volumetric shrinkage of sample B2 reduced when the temperature was raised from 1300°C to 1500°C. It is observed that the volumetric shrinkage of sample B2 is lower than B1 at all temperatures. This is because the carbon content of sample B1 is higher than sample B2. The limited shrinkage recorded makes the composite suitable for high temperature applications. According to Gupta, (2010) [31], a refractory material should be able to maintain sufficient dimensional stability at high temperatures and after/during repeated thermal cycling.

CONCLUSIONS
From the discussed data it is concluded that;

- mullite and cristobalite (a polymorph of silica) contents of the samples generally increased with increased sintering temperature;
- addition of titania improves on the densification of the samples at various sintering temperatures;
- the addition of 4 vol. % titania to the sample aids densification at relatively lower sintering temperature than when 2 vol. % titania is added;
- the addition of 4 vol. % titania to the sample improves on the cold crushing strength of the samples sintered at relatively lower sintering temperature than when 2 vol. % titania is added;
- 2 vol. % titania in the sample leads to progressive increased volumetric shrinkage as the sintering temperature increased while, 4 vol. % titania leads to reduction in the volumetric shrinkage with increased sintering temperature;
- the optimum mechanical property of the ceramic samples produced was achieved with sample that contain 4 (vol.) % titania and sintered at 1300°C.

Acknowledgments
The authors acknowledge the Science Initiative Group (SIG), based at the Institute for Advanced Study in Princeton, for the support of this research work through the Competitive Fund for Rise Graduates Phase I (Round 1 and 3). Without this fund, it would have been extremely difficult to achieve the objectives of this research work.
